Sub 317
a1
--A multi-carrier transmission system which exchanges control information between a transmitter and a receiver. The information is generated in the receiver and terminated in the transmitter. The information includes data with all the instantaneous characteristics of the channel and information about system change decisions needed to handle the change in channel characteristics. In systems that use bit-loading techniques, the number of transmitted bits per symbol is adapted to the signal-to-noise ratio of the current carrier wave. This regulation dynamically affects in time the total bandwidth of the system. This variation in bandwidth leads to an absolute system requirement for synchronous configuration of the transmitter and the receiver, in terms of the number of coded/decoded bits per symbol and carrier wave. This requirement must be met so that the system can maintain a connection.--
